Problem 1.1 (Taylor's formula)

Let $f: \mathbb{R}^n \rightarrow \mathbb{R}$ be smooth, $n \geq 2$. Prove that

$$f(x) = \sum_{|\alpha| \leq k} \frac{1}{\alpha!} D^\alpha f(0) x^\alpha + O(|x|^{k+1})$$

as $x \rightarrow 0$ for each $k = 1, 2, \dots$, assuming that you know this formula for $n = 1$.

Hint: Fix $x \in \mathbb{R}^n$ and consider the function of one variable $g(t) := f(tx)$. Prove that

$$\frac{d^m}{dt^m} g(t) = \sum_{|\alpha|=m} \frac{m!}{\alpha!} D^\alpha f(tx) x^\alpha,$$

by induction on m .

Solution. ► Taking the hint, fix $x \in \mathbb{R}^n$ and consider the function of one variable $g(t) := f(tx)$. We claim that

$$\frac{d^m}{dt^m} g(t) = \sum_{|\alpha|=m} \frac{m!}{\alpha!} D^\alpha f(tx) x^\alpha.$$

Proof of claim. We shall proceed by induction on m . The case $m = 1$ follows easily from the chain rule:

$$\begin{aligned} \frac{d}{dt} g(t) &= \frac{d}{dt} f(tx) \\ &= D^{(1,0,\dots,0)} f(tx) x_1 + \dots + D^{(0,\dots,0,1)} f(tx) x_n \\ &= (D^{(1,0,\dots,0)} x_1 + \dots + D^{(0,\dots,0,1)} x_n) f(tx) \end{aligned}$$

which we can write compactly as

$$= \sum_{|\alpha|=1} \frac{1!}{\alpha!} D^\alpha f(tx) x^\alpha.$$

Now, assume the result for $n \leq m - 1$. Then

$$\begin{aligned} \frac{d^m}{dt^m} g(t) &= \frac{d}{dt} \left[\frac{d^{m-1}}{dt^{m-1}} g(t) \right] \\ &= \frac{d}{dt} \left[\sum_{|\alpha|=m-1} \frac{(m-1)!}{\alpha!} D^\alpha f(tx) x^\alpha \right] \end{aligned}$$

since the derivative is a linear operator, we have

$$\begin{aligned} &= \sum_{|\alpha|=m-1} \frac{(m-1)!}{\alpha!} \frac{d}{dt} [D^\alpha f(tx) x^\alpha] \\ &= \sum_{|\alpha|=m-1} \frac{(m-1)!}{\alpha!} \sum_{|\beta|=1} D^{\alpha+\beta} f(tx) x^{\alpha+\beta} \end{aligned}$$

but since f is smooth, the order in which we take derivatives does not matter and, hence the operators commute giving us

$$= \left[\sum_{|\beta|=1} (Dx)^\beta \sum_{|\alpha|=m-1} \frac{(m-1)!}{\alpha!} (Dx)^\alpha \right] f(tx). \quad (1.1)$$

From here it suffices to do some combinatorics on the operators and reduce it to the desired expression. By the multinomial theorem, we have

$$\left(\sum_{|\alpha'|=1} (Dx)^{\alpha'} \right)^{m-1} = \sum_{|\alpha|=m-1} \binom{|\alpha|}{\alpha} (Dx)^\alpha = \sum_{|\alpha|=m-1} \frac{(m-1)!}{\alpha!} (Dx)^\alpha.$$

Thus (1.1) becomes

$$\begin{aligned} \left[\sum_{|\beta|=1} (Dx)^\beta \sum_{|\alpha|=m-1} \frac{(m-1)!}{\alpha!} (Dx)^\alpha \right] f(tx) &= \left[\sum_{|\beta|=1} (Dx)^\beta \left(\sum_{|\alpha'|=1} (Dx)^{\alpha'} \right)^{m-1} \right] f(tx) \\ &= \left[\left(\sum_{|\beta|=1} (Dx)^\beta \right)^m \right] f(tx) \\ &= \sum_{|\alpha|=m} \frac{m!}{\alpha!} (Dx)^\alpha f(tx) \\ &= \sum_{|\alpha|=m} \frac{m!}{\alpha!} D^\alpha f(tx) x^\alpha, \end{aligned}$$

as desired. □

Now, applying Taylor's formula in 1 variable to $g(t)$ and evaluating at $t = 1$ we have

$$\begin{aligned} f(x) &= g(1) \\ &= \sum_{i=0}^k \frac{g^{(i)}(0)}{i!} 1^i + O(|x|^{k+1}) \\ &= \sum_{i=0}^k \frac{1}{i!} \sum_{|\alpha|=i} \frac{i!}{\alpha!} D^\alpha f(0) x^\alpha + O(|x|^{k+1}) \\ &= \sum_{i=0}^k \sum_{|\alpha|=i} \frac{1}{\alpha!} D^\alpha f(0) x^\alpha + O(|x|^{k+1}) \\ &= \sum_{|\alpha| \leq k} \frac{1}{\alpha!} D^\alpha f(0) x^\alpha + O(|x|^{k+1}) \end{aligned}$$

as desired. ◀

Problem 1.2

Write down the characteristic equation for the PDE

$$u_t + b \cdot Du = f \quad (*)$$

on $\mathbb{R}^n \times (0, \infty)$, where $b \in \mathbb{R}^n$. Using the characteristic equation, solve (*) subject to the initial condition

$$u = g$$

on $\mathbb{R}^n \times \{t = 0\}$. Make sure the answer agrees with formula (5) in §2.1.2 of [E].

Solution. ► For reference, formula (5) in §2.1.2 of [E] is the solution to the nonhomogeneous problem

$$u(\mathbf{x}, t) = g(\mathbf{x} - t\mathbf{b}) + \int_0^t f(\mathbf{x} + (s - t)\mathbf{b}, s) ds$$

where $\mathbf{x} \in \mathbb{R}^n$, $t > 0$.

To make the notation more bearable, we will use \mathbf{b} and \mathbf{x} to denote the original vectors in (*). First, we write (*) as the directional derivative along $(\mathbf{b}, 1)$, (note the abuse of notation)

$$\begin{aligned} f &= u_t + \mathbf{b} \cdot Du \\ &= (\mathbf{b}, 1) \cdot Du. \end{aligned}$$

Using the structure of characteristic ODE, we have the PDE

$$F(p, z, x) = (\mathbf{b}, 1) \cdot p$$

with characteristics

$$\dot{x} = b, \quad \dot{t} = 1, \quad \dot{z} = f.$$

Now, given a point $(\mathbf{x}, t) \in \mathbb{R}^n \times (0, \infty)$ we can solve the ODEs \dot{x} and \dot{t} easily as the lines $x(s) = \mathbf{x} - \mathbf{b}t + \mathbf{b}s$ and $t = s$. Substituting these solutions into \dot{z} , we have

$$\dot{z} = f(x(s), t(s)) = f(\mathbf{x} + \mathbf{b}(s - t), s)$$

so

$$\begin{aligned} \int_0^t f(x(s), t(s)) ds &= \int_0^t f(\mathbf{x} + \mathbf{b}(s - t), s) ds = \int_0^t \dot{z} ds \\ &= z(t) - z(0) \\ &= u(\mathbf{x}, t) - u(\mathbf{x} - \mathbf{b}t, 0). \end{aligned}$$

Thus,

$$\begin{aligned} u(\mathbf{x}, t) &= u(\mathbf{x} - \mathbf{b}t, 0) + \int_0^t f(x(s), t(s)) ds = f(\mathbf{x} + \mathbf{b}(s - t), s) ds \\ &= g(\mathbf{x} - \mathbf{b}t) + \int_0^t f(x(s), t(s)) ds = f(\mathbf{x} + \mathbf{b}(s - t), s) ds \end{aligned}$$

as desired. ◀

Problem 1.3

Solve using the characteristics:

- (a) $x_1^2 u_{x_1} + x_2^2 u_{x_2} = u^2$, $u = 1$ on the line $x_2 = 2x_1$.
 (b) $uu_{x_1} + u_{x_2} = 1$, $u(x_1, x_1) = x_1/2$.
 (c) $x_1 u_{x_1} + 2x_2 u_{x_2} + u_{x_3} = 3u$, $u(x_1, x_2, 0) = g(x_1, x_2)$.

Solution. ► For part (a), employing the method of characteristics, we write

$$F(p, z, x) = (x_1^2, x_2^2) \cdot p = z^2.$$

From here, we have

$$\dot{x} = (x_1^2, x_2^2), \quad \dot{z} = z^2.$$

Now say $x(0) = (2t', t')$ and solve for \dot{x} ,

$$\begin{aligned} \int_0^t ds &= \int_0^t \frac{1}{x_1(s)^2} dx_1(s) & \int_0^t ds &= \int_0^t \frac{1}{x_2(s)^2} dx_2(s) \\ t &= -\frac{1}{x_1(t)} + \frac{1}{x_1(0)} & t &= -\frac{1}{x_2(t)} + \frac{1}{x_2(0)} \\ x_1(t) &= \frac{1}{1/x_1(0) - t} & x_2(t) &= \frac{1}{1/x_2(0) - t} \\ &= \frac{2t'}{1 - 2tt'} & &= \frac{t'}{1 - tt'}. \end{aligned}$$

Thus,

$$x(t) = \left(\frac{2t'}{1 - 2tt'}, \frac{t'}{1 - tt'} \right)$$

and solving for z similarly yields

$$z(t) = \frac{z(0)}{1 - tz(0)} = \frac{1}{1 - t}$$

since $z = u^2 = 1$ on the line $x_2 = 2x_1$. Lastly, solving for t in terms of x_1 and x_2 , we have

$$\begin{aligned} t' &= \frac{x_1}{2(tx_1 + 1)} \\ &= \frac{x_2}{tx_2 + 1} \end{aligned}$$

which, with a little algebra, can be turned into

$$t = \frac{1 - 2x_2/x_1}{x_2} = \frac{x_2 - 2x_1}{x_1 x_2}.$$

Now substituting this into the solution $z(t)$, we have

$$\begin{aligned} u(x, y) &= z(t) \\ &= \frac{1}{1-t} \\ &= \frac{1}{1 - (x_2 - 2x_1)/(x_1 x_2)} \\ &= \frac{x_1 x_2}{x_1 x_2 - x_2 + 2x_1}. \end{aligned}$$

For part (b), write

$$F(p, z, x) = (z, 1) \cdot p = 1.$$

Then, we have

$$\dot{x} = (z, 1), \quad \dot{z} = 1.$$

From here, fix $x^0 \in \mathbb{R}$ and reparameterize $x(t)$ such $x(0) = (x^0, x^0)$ then solutions have the form

$$\begin{aligned} x_1(t) &= \frac{t^2}{2} + \frac{x^0}{2}t + x^0, & x_2(t) &= t + x^0, \\ z(t) &= t + x^0/2. \end{aligned}$$

Now, solve for t in terms of x_1, x_2 (using the square root formula), we have

$$t = -\left(\frac{x^0}{2} - 1\right) \pm \sqrt{\left(\frac{x^0}{2} - 1\right)^2 - 2x_2}$$

For part (c), we have

$$F(p, z, x) = (x_1, 2x_2, 1) \cdot p = 3z.$$

Then

$$\dot{x} = (x_1, 2x_2, 1), \quad \dot{z} = 3z.$$

From here, reparameterize $x_3(t)$ such $x_3(0) = 0$ then solutions have the form

$$\begin{aligned} x_1(t) &= x'_1 e^t, & x_2(t) &= x'_2 e^{2t}, \\ x_3(t) &= t, & z(t) &= g(x'_1, x'_2) e^{3t}. \end{aligned}$$

Then the solution has the form

$$\begin{aligned} u(x_1, x_2, x_3) &= z(t) \\ &= g(x'_1, x'_2) e^{3x_3} \end{aligned}$$

◀

Problem 1.4

For the equation

$$u = x_1 u_{x_1} + x_2 u_{x_2} + \frac{1}{2}(u_{x_1}^2 + u_{x_2}^2)$$

find a solution with $u(x_1, 0) = (1 - x_1^2)/2$.

Solution. ► By inspection, the PDE looks like should be separable, so suppose we have a solution of the form

$$u(x_1, x_2) = u_1(x_1) + u_2(x_2).$$

Then

$$u_1(x_1) + u_2(x_2) = x_1 \dot{u}_1(x_1) + x_2 \dot{u}_2(x_2) + \frac{1}{2} \left(\dot{u}_1(x_1)^2 + \dot{u}_2(x_2)^2 \right).$$

Now we solve u_1 and u_2 separately. For u_1 , we have

$$u_1 = x_1 \dot{u}_1(x_1) + \frac{1}{2} \dot{u}_1(x_1)^2$$

which has a solution of the form

$$ax_1^2 + bx_1 + c.$$

Plugging this in, we have

$$\begin{aligned} ax_1^2 + bx_1 + c &= x_1(2ax_1 + b) + a \\ &= 2ax_1^2 + bx_1 + a. \end{aligned}$$

so $a = c = 0$ and the solution is of the form $u_1(x_1) = bx_1$. Similarly, for $u_2(x_2)$, we have $u_2(x_2) = b'x_2$. ◀
