Problem 1.1 (Taylor's formula)

Let $f \colon \mathbb{R}^n \to \mathbb{R}$ be smooth, $n \geq 2$. Prove that

$$f(x) = \sum_{|\alpha| \leq k} \frac{1}{\alpha!} D^\alpha f(0) x^\alpha + \mathrm{O}\big(|x|^{k+1}\big)$$

as $x \to \mathbf{0}$ for each $k = 1, 2, \ldots$, assuming that you know this formula for $n = 1$.

Hint: Fix $x \in \mathbb{R}^n$ and consider the function of one variable $g(t) := f(tx)$. Prove that

$$\frac{d^m}{dt^m} g(t) = \sum_{|\alpha| = m} \frac{m!}{\alpha!} D^\alpha f(tx) x^\alpha,$$

by induction on m.

Solution. ▶ Taking the hint, fix $x \in \mathbb{R}^n$ and consider the function of one variable $g(t) := f(tx)$. We claim that

$$\frac{d^m}{dt^m} g(t) = \sum_{|\alpha| = m} \frac{m!}{\alpha!} D^\alpha f(tx) x^\alpha.$$

Proof of claim. We shall proceed by induction on m. The case $m = 1$ follows easily from the chain rule:

$$\begin{aligned}
\frac{d}{dt} g(t) &= \frac{d}{dt} f(tx) \\
&= D^{(1,0,\ldots,0)} f(tx) x_1 + \cdots + D^{(0,\ldots,0,1)} f(tx) x_n \\
&= \big(D^{(1,0,\ldots,0)} x_1 + \cdots + D^{(0,\ldots,0,1)} x_n\big) f(tx)
\end{aligned}$$

which we can write compactly as

$$= \sum_{|\alpha| = 1} \frac{1!}{\alpha!} D^\alpha f(tx) x^\alpha.$$

Now, assume the result for $n \leq m - 1$. Then

$$\begin{aligned}
\frac{d^m}{dt^m} g(t) &= \frac{d}{dt} \left[\frac{d^{m-1}}{dt^{m-1}} g(t) \right] \\
&= \frac{d}{dt} \left[\sum_{|\alpha| = m-1} \frac{(m-1)!}{\alpha!} D^\alpha f(tx) x^\alpha \right]
\end{aligned}$$

since the derivative is a linear operator, we have

$$\begin{aligned}
&= \sum_{|\alpha| = m-1} \frac{(m-1)!}{\alpha!} \frac{d}{dt} \big[D^\alpha f(tx) x^\alpha \big] \\
&= \sum_{|\alpha| = m-1} \frac{(m-1)!}{\alpha!} \sum_{|\beta| = 1} D^{\alpha+\beta} f(tx) x^{\alpha+\beta}
\end{aligned}$$

but since f is smooth, the order in which we take derivatives does not matter and, hence the operators commute giving us

$$= \left[\sum_{|\beta|=1} (Dx)^\beta \sum_{|\alpha|=m-1} \frac{(m-1)!}{\alpha!} (Dx)^\alpha \right] f(tx). \tag{1.1}$$

From here it suffices to do some combinatorics on the operators and reduce it to the desired expression. By the multinomial theorem, we have

$$\left(\sum_{|\alpha'|=1} (Dx)^{\alpha'} \right)^{m-1} = \sum_{|\alpha|=m-1} \binom{|\alpha|}{\alpha} (Dx)^\alpha = \sum_{|\alpha|=m-1} \frac{(m-1)!}{\alpha!} (Dx)^\alpha.$$

Thus (**??**) becomes

$$\left[\sum_{|\beta|=1} (Dx)^\beta \sum_{|\alpha|=m-1} \frac{(m-1)!}{\alpha!} (Dx)^\alpha \right] f(tx) = \left[\sum_{|\beta|=1} (Dx)^\beta \left(\sum_{|\alpha'|=1} (Dx)^{\alpha'} \right)^{m-1} \right] f(tx)$$

$$= \left[\left(\sum_{|\beta|=1} (Dx)^\beta \right)^m \right] f(tx)$$

$$= \sum_{|\alpha|=m} \frac{m!}{\alpha!} (Dx)^\alpha f(tx)$$

$$= \sum_{|\alpha|=m} \frac{m!}{\alpha!} D^\alpha f(tx) x^\alpha,$$

as desired.   □

Now, applying Taylor's formula in 1 variable to $g(t)$ and evaluating at $t = 1$ we have

$$f(x) = g(1)$$

$$= \sum_{i=0}^{k} \frac{g^{(i)}(0)}{i!} 1^i + \mathrm{O}(|x|^{k+1})$$

$$= \sum_{i=0}^{k} \frac{1}{i!} \sum_{|\alpha|=i} \frac{i!}{\alpha!} D^\alpha f(tx) x^\alpha + \mathrm{O}(|x|^{k+1})$$

$$= \sum_{i=0}^{k} \sum_{|\alpha|=i} \frac{1}{\alpha!} D^\alpha f(0) x^\alpha + \mathrm{O}(|x|^{k+1})$$

$$= \sum_{|\alpha| \le k} \frac{1}{\alpha!} D^\alpha f(0) x^\alpha + \mathrm{O}(|x|^{k+1})$$

as desired.   ◀

Problem 1.2

Write down the characteristic equation for the PDE

$$u_t + b \cdot Du = f \qquad\qquad (*)$$

on $\mathbb{R}^n \times (0, \infty)$, where $b \in \mathbb{R}^n$. Using the characteristic equation, solve (??) subject to the initial condition

$$u = g$$

on $\mathbb{R}^n \times \{t = 0\}$. Make sure the answer agrees with formula (5) in §2.1.2 of [E].

Solution. ▶ For reference, formula (5) in §2.1.2 of [E] is the solution to the nonhomogeneous problem

$$u(\mathbf{x}, t) = g(\mathbf{x} - t\mathbf{b}) + \int_0^1 f\left(\mathbf{x} + (s - t)\mathbf{b}, s\right) ds$$

where $\mathbf{x} \in \mathbb{R}^n$, $t > 0$.

To make the notation more bearable, we will use $\mathbf{b}$ and $\mathbf{x}$ to denote the original vectors in (??). First, we write (??) as the directional derivative along $(\mathbf{b}, 1)$, (note the abuse of notation)

$$\begin{aligned}
f &= u_t + \mathbf{b} \cdot Du \\
&= (\mathbf{b}, 1) \cdot Du.
\end{aligned}$$

Using the structure of characteristic ODE, we have the PDE

$$F(p, z, x) = (\mathbf{b}, 1) \cdot p$$

with characteristics

$$\dot{x} = b, \qquad \dot{t} = 1, \qquad \dot{z} = f.$$

Now, given a point $(\mathbf{x}, t) \in \mathbb{R}^n \times (0, \infty)$ we can solve the ODEs $\dot{x}$ and $\dot{t}$ easily as the lines $x(s) = \mathbf{x} - \mathbf{b}t + \mathbf{b}s$ and $t = s$. Substituting these solutions into $\dot{z}$, we have

$$\dot{z} = f\left(x(s), t(s)\right) = f\left(\mathbf{x} + \mathbf{b}(s - t), s\right)$$

so

$$\begin{aligned}
\int_0^t f\left(x(s), t(s)\right) = f\left(\mathbf{x} + \mathbf{b}(s - t), s\right) ds &= \int_0^t \dot{z} \, ds \\
&= z(t) - z(0) \\
&= u(\mathbf{x}, t) - u(\mathbf{x} - \mathbf{b}t, 0).
\end{aligned}$$

Thus,

$$\begin{aligned}
u(\mathbf{x}, t) &= u(\mathbf{x} - \mathbf{b}t, 0) + \int_0^t f\left(x(s), t(s)\right) = f\left(\mathbf{x} + \mathbf{b}(s - t), s\right) ds \\
&= g(\mathbf{x} - \mathbf{b}) + \int_0^t f\left(x(s), t(s)\right) = f\left(\mathbf{x} + \mathbf{b}(s - t), s\right) ds
\end{aligned}$$

as desired.   ◀

Problem 1.3

Solve using the characteristics:

(a) $x_1^2 u_{x_1} + x_2^2 u_{x_2} = u^2$, $u = 1$ on the line $x_2 = 2x_1$.

(b) $uu_{x_1} + u_{x_2} = 1$, $u(x_1, x_1) = x_1/2$.

(c) $x_1 u_{x_1} + 2x_2 u_{x_2} + u_{x_3} = 3u$, $u(x_1, x_2, 0) = g(x_1, x_2)$.

Solution. ▶ For part (a), employing the method of characteristics, we write

$$F(p, z, x) = \left(x_1^2, x_2^2\right) \cdot p = z^2.$$

From here, we have

$$\dot{x} = \left(x_1^2, x_2^2\right), \qquad \dot{z} = z^2.$$

Now say $x(0) = (2t', t')$ and solve for $\dot{x}$,

$$\int_0^t ds = \int_0^t \frac{1}{x_1(s)^2} dx_1(s) \qquad\qquad \int_0^t ds = \int_0^t \frac{1}{x_1(s)^2} dx_1(s)$$

$$t = -\frac{1}{x_1(t)} + \frac{1}{x_1(0)} \qquad\qquad t = -\frac{1}{x_2(s)} + \frac{1}{x_2(0)}$$

$$x_1(t) = \frac{1}{1/x_1(0) - t} \qquad\qquad x_2(t) = \frac{1}{1/x_2(0) - t}$$

$$= \frac{2t'}{1 - 2tt'} \qquad\qquad = \frac{t'}{1 - tt'}.$$

Thus,

$$x(t) = \left(\frac{2t'}{1 - 2tt'}, \frac{t'}{1 - tt'}\right)$$

and solving for z similarly yields

$$z(t) = \frac{z(0)}{1 - tz(0)} = \frac{1}{1 - t}$$

since $z = u^2 = 1$ on the line $x_2 = 2x_1$. Lastly, solving for t in terms of x_1 and x_2, we have

$$t' = \frac{x_1}{2(tx_1 + 1)}$$

$$= \frac{x_2}{tx_2 + 1}$$

which, with a little algebra, can be turned into

$$t = \frac{1 - 2x_2/x_1}{x_2} = \frac{x_2 - 2x_1}{x_1 x_2}.$$

Now substituting this into the solution $z(t)$, we have

$$u(x, y) = z(t)$$
$$= \frac{1}{1 - t}$$
$$= \frac{1}{1 - (x_2 - 2x_1)/(x_1 x_2)}$$
$$= \frac{x_1 x_2}{x_1 x_2 - x_2 + 2x_1}.$$

For part (b), write

$$F(p, z, x) = (z, 1) \cdot p = 1.$$

Then, we have

$$\dot{x} = (z, 1), \qquad \dot{z} = 1.$$

From here, fix $x^0 \in \mathbb{R}$ and reparameterize $x(t)$ such $x(0) = (x^0, x^0)$ then solutions have the form

$$x_1(t) = \frac{t^2}{2} + \frac{x^0}{2} t + x^0, \qquad\qquad x_2(t) = t + x^0,$$
$$z(t) = t + x^0/2.$$

Now, solve for t in terms of x_1, x_2 (using the square root formula), we have

$$t = -\left(\frac{x^0}{2} - 1\right) \pm \sqrt{\left(\frac{x^0}{2} - 1\right)^2 - 2x_2}$$

For part (c), we have

$$F(p, z, x) = \left(x_1, 2x_2, 1\right) \cdot p = 3z.$$

Then

$$\dot{x} = (x_1, 2x_2, 1), \qquad \dot{z} = 3z.$$

From here, reparameterize $x_3(t)$ such $x_3(0) = 0$ then solutions have the form

$$x_1(t) = x_1' e^t, \qquad\qquad x_2(t) = x_2' e^{2t},$$
$$x_3(t) = t, \qquad\qquad z(t) = g(x_1', x_2') e^{3t}.$$

Then the solution has the form

$$u(x_1, x_2, x_3) = z(t)$$
$$= g(x_1', x_2') e^{3x_3}$$

◄

Problem 1.4

For the equation

$$u = x_1 u_{x_1} + x_2 u_{x_2} + \frac{1}{2}\left(u_{x_1}^2 + u_{x_2}^2\right)$$

find a solution with $u(x_1, 0) = \left(1 - x_1^2\right)/2$.

Solution. ▶ By inspection, the PDE looks like should be separable, so suppose we have a solution of the form

$$u(x_1, x_2) = u_1(x_1) + u_2(x_2).$$

Then

$$u_1(x_1) + u_2(x_2) = x_1 \dot{u}_1(x_1) + x_2 \dot{u}_2(x_2) + \frac{1}{2}\left(\dot{u}_1(x_1)^2 + \dot{u}_2(x_2)^2\right).$$

Now we solve u_1 and u_2 separately. For u_1, we have

$$u_1 = x_1 \dot{u}_1(x_1) + \frac{1}{2}\dot{u}(x_1)^2$$

which has a solution of the form

$$ax_1^2 + bx_1 + c.$$

Plugging this in, we have

$$\begin{aligned} ax_1^2 + bx_1 + c &= x_1(2ax_1 + b) + a \\ &= 2ax_1^2 + bx_1 + a. \end{aligned}$$

so $a = c = 0$ and the solution is of the form $u_1(x_1) = bx_1$. Similarly, for $u_2(x_2)$, we have $u_2(x_2) = b'x_2$. ◄
